

¹ (In)sensitivity to surface-level heuristics: A case from
² Turkish verbal attractors

³ Anonymous

⁴ **Abstract**

⁵ Linguistic illusion literature debates what information accesses memory representations. Prior work
⁶ tests whether structural, semantic, or discourse cues guide subject-verb dependencies; however, it
⁷ remains unclear whether native speakers rely on surface level heuristics, such as phonological infor-
⁸ mation during dependency resolution. Traditionally, accidental phonological resemblance to plural
⁹ ending (e.g., the /s/ in *cruise*) does not induce erroneous agreement in English, whereas resem-
¹⁰ blance correlating with controllerhood amplifies attraction across varies languages. Contradicting
¹¹ this generalization, Slioussar (2018) proposed that accidental phonological resemblance can mediate
¹² memory search for Russian subjects. Given the theoretical importance of this proposal and the lack
¹³ of comparable effects in other languages such as Czech, we propose re-interpret previous findings
¹⁴ under the light of a recently growing literature of association with being a possible controller. We
¹⁵ test whether phonological overlap or association with controllerhood elicits erroneous agreement in
¹⁶ Turkish. Turkish provides a critical test: both verbal and nominal elements can surface as subjects
¹⁷ and the plural morpheme *-lAr* marks number in both of them, but only nominal plural *-lAr* con-
¹⁸ trols verbal agreement. Two speeded acceptability studies show no attraction from plural-marked
¹⁹ verbs ($N = 80$; $N = 95$) but robust attraction from genitive plural nouns. We report a first-of-
²⁰ its-kind dissociation under minimal manipulation: verbal attractors that can surface as subjects
²¹ yet cannot control agreement do not induce attraction, whereas genitive plural nouns—which can
²² be subjects and control in other environments—do. This pattern constrains retrieval processes by
²³ tying attraction to abstract controller features rather than surface phonology.

²⁵ ing

26 1 Introduction

27 Human sentence processing draws both on abstract grammatical features and heuristics that ex-
28 ploit surface regularities, such as plausibility (Speer and Clifton, 1998), frequency (Lau et al., 2007),
29 and task-specific factors (Laurinavichyute and von der Malsburg, 2024; Arehalli and Wittenberg,
30 2021; Hammerly et al., 2019; Logačev and Vasishth, 2016). We focus on one such heuristic: over-
31 reliance on surface form, evidenced when phonological similarity between sentence constituents is
32 observed to modulate performance (Acheson and MacDonald, 2011; Kush et al., 2015; Copeland
33 and Radvansky, 2001; Rastle and Davis, 2008). Prior work shows reliable slowdowns and compre-
34 hension accuracy costs due to surface-form overlap. However, it is unresolved whether this heuristic
35 penetrates dependency resolution itself—including subject-verb agreement, pronoun resolution, or
36 the licensing of negative polarity items—beyond general effects on reading ease and memory. The
37 few studies that bear directly on subject-verb agreement exhibit contradictory findings (Bock and
38 Eberhard, 1993; Slioussar, 2018; Lacina and Chromý, 2022).

39 A central question for understanding human cognition is what information is encoded and later
40 available in memory during comprehension, and how faithful these encodings are to the input.
41 ‘Good-Enough’ and noisy channel accounts argue that detailed analyses are not always maintained
42 when heuristics suffice, creating the opportunity for surface regularities to affect judgments (Ferreira
43 et al., 2002). More specifically, general cue-based retrieval approaches hold that constituents are
44 stored with detailed abstract features and later accessed by matching retrieval cues, and that
45 erroneous parses can occur when features conflict or interfere. However, it remains open whether
46 phonological codes are used as such cues during syntactic dependency building (Lewis and Vasishth,
47 2005). Determining whether surface-form overlap modulates dependency resolution provides a
48 window into what human cognition counts as diagnostic information for retrieving dependency
49 controllers and how faithful the stored representations are.

50 Agreement is an ideal case study because its computations are known to be sensitive to feature
51 overlap. Classic findings demonstrate systematic errors in establishing number agreement between
52 a verb and its agreement controller when an NP with a different number (the attractor) interferes.
53 Speakers produce sentences like (1) or misclassify them as acceptable (Bock and Miller, 1991;
54 Pearlmuter et al., 1999).

55 (1) * The player on the courts are tired from a long-game.

56 Despite much research on what factors modulate agreement errors, the role of phonology remains
57 unclear. Pseudoplural attractors whose final phone matches the plural suffix and string-ambiguous
58 with other nouns (e.g. *cruise* vs. *crews*) do not increase agreement errors in production (Bock and
59 Eberhard, 1993). Phonological overlap effects have been observed in other cases, but many of them
60 involve additional shared morphological features (Hartsuiker et al., 2003; Lago et al., 2019; Bleotu
61 and Dillon, 2024; Lacina and Chromý, 2022), although not all (Slioussar, 2018). This raises the
62 possibility that surface form affects the formation of agreement dependencies not directly through
63 the use of number form as a retrieval cue, but indirectly, when the surface form is one that is more

64 likely to be realized on agreement controllers.

65 We test this hypothesis by utilizing the surface-form overlap between the verbal and nominal
66 morphological reflexes of agreement in Turkish. Turkish uses the same surface suffix, *-lAr*, for
67 plural marking on nouns and for plural agreement on finite verbs. Crucially, strings bearing verbal
68 *-lAr* can occur in subject position, yet they never control finite clause agreement; only nominal
69 plurals do. These properties allow us to test whether form overlap is sufficient to drive attraction,
70 or if the attractor must also be a possible controller (true of nouns but not verbs). Across two
71 high-powered speeded acceptability experiments in Turkish we find that plural marking on an
72 embedded verbal attractor does not increase acceptance of plural agreement on the matrix verb;
73 such effects are only observed when the plural marker appears on a non-subject noun attractor.
74 These results indicate that surface-form overlap alone does not function as a retrieval cue for
75 agreement in Turkish. Dependency resolution relies on abstract features and structural relations,
76 with phonology influencing processing primarily outside of retrieval.

77 1.1 Background

78 Agreement has been a central domain of investigation for language processing research on memory.
79 Though ubiquitous (296 of out 378 languages surveyed exhibit agreement, see Siewierska, 2013 for
80 the discussion), this process is not always reliable. In their seminal work, Bock and Miller (1991)
81 showed that participants produce reliably more erroneous non-controller-matching plural verb forms
82 in English with an embedded plural ‘attractor’—for example, producing a plural continuation more
83 often after (2b) than (2a). The effect of the number mismatch, agreement attraction, has also been
84 found to be robust in comprehension (Nicol et al., 1997; Pearlmuter et al., 1999) of such sentences
85 in various languages, including Arabic (Tucker et al., 2015), Armenian (Avetisyan et al., 2020),
86 Bulgarian (Ivanova-Sullivan et al., 2024), Hindi (Bhatia and Dillon, 2022), Spanish (Lago et al.,
87 2015), Russian (Slioussar, 2018), and Turkish (Lago et al., 2019; Türk and Logačev, 2024; Ulusoy,
88 2023).

89 (2) a. Singular Attractor

90 The ship for the crew ...

91 b. Plural Attractor

92 The ship on the crews ...

93 Many studies have investigated the various syntactic and semantic factors which make agreement
94 errors more likely, which include hierarchical distance (Hartsuiker et al., 2001; Nicol et al., 1997;
95 Kaan, 2002), linear distance (Bock and Cutting, 1992; but see Pearlmuter, 2000; Kwon and Sturt,
96 2019), semantic interactions of nouns involved (Eberhard, 1999; Vigliocco et al., 1995; Humphreys
97 and Bock, 2005), and syntactic category of the phrase containing the attractor (Bock and Miller,
98 1991; Bock and Cutting, 1992). One widely accepted set of accounts that explained these errors are
99 called retrieval based theories (Lewis and Vasishth, 2005; Wagers et al., 2009). In these accounts,

100 comprehenders maintain faithful linguistic representations; errors arise because the memory mech-
101 anisms used to identify the agreement controller mislead them. Under this approach, phrases are
102 encoded in content-addressable memory as *chunks*—bundles of features including number, gender,
103 and syntactic properties (Smith and Vasishth, 2020). Comprehenders predict the number of the
104 verb based on the noun phrases they process while reading the previous noun phrases. In grammatical
105 sentences with singular verb agreement, the number prediction and the verb number match,
106 which causes no processing difficulty. In contrast, when participants fail to find the predicted num-
107 ber morphology on the verb, a memory-retrieval process is initiated. This process activates the
108 search for a chunk matching relevant cues for agreement controller.

109 What is the characteristics of cues which are found useful to be encoded? One line of work
110 manipulated overt case marking on attractors to test whether morphophonological case is used
111 for dependency resolution. For example, Hartsuiker et al. (2003) used the syncretic homophony
112 between nominative/accusative and singular/plural forms of feminine determiners in German, com-
113 paring these ambiguous forms to distinctly marked dative forms. Participants produced more agree-
114 ment errors when the preambles contained two noun phrases whose determiners were ambiguously
115 marked (*die*), compared to cases where the attractor case could be distinguished by form alone
116 (*den*). Furthermore, this additive effect was limited to feminine nouns, the only gender show-
117 ing nominative–accusative syncretism in plural forms, while nouns of other grammatical genders
118 showed the base effect of plural.

119 However, results from other case-marking languages are mixed. In French, Franck et al. (2010)
120 found that unambiguous accusative marking increased attraction, contrary to the prediction that
121 reduced ambiguity limits interference. Avetisyan et al. (2020) observed that unambiguous case in
122 Armenian modulated neither reading times nor error rates. Conversely, Lacina et al. (2025) found
123 that attraction in Czech and Slovak surfaced only when case morphology was ambiguous. These
124 findings suggest that distinct case morphology is insufficient to predict interference, implicating
125 language-specific distributions or heuristic processing.

126 A second line of work tests phonological overlap that does not itself change the syntactic analysis.
127 Bock and Eberhard (1993) tested whether attractors that only sound plural, pseudoplural singular
128 attractors such as *course*, increase agreement errors compared to true plural nouns, such as *courts*
129 in (2b). They reasoned that if participants rely on phonological cues rather than abstract features,
130 words ending with plural-like sounds (/s/ or /z/) should behave like true plurals. In their preamble
131 completion study, they found that pseudoplural attractors did not induce agreement errors, which
132 argues against a purely phonology-driven account of attraction in English.

133 In contrast, Slioussar (2018) reported a contribution of surface-form overlap to agreement in
134 Russian. In Russian, a subset of genitive singular nouns is homophonous with nominative plural
135 forms, while genitive plural forms are not ambiguous in this way. In a series of production and com-
136 prehension experiments, Slioussar (2018) showed that sentences with a singular genitive attractor
137 whose form overlaps with nominative plural yielded more plural completions, faster reading times
138 at the plural verb and higher rates of acceptability compared to the sentences with unambiguous

¹³⁹ genitive plural attractors. Slioussar (2018) took these results to be an evidence for a retrieval pro-
¹⁴⁰ cess in which the search for a controller is mediated through phonological form and relevant features
¹⁴¹ like +NOM and +PL can be activated. However, the same surface-form overlap did not give rise
¹⁴² to attraction effects in Czech, another Slavic language (Lacina and Chromy, 2022). These mixed
¹⁴³ findings in case-syncretism literature, English pseudoplural, and a failure to replicate in another
¹⁴⁴ Slavic language cast a shadow on phonological modulation explanation.

¹⁴⁵ An alternative account posits that instead of phonological feature activation, errors arise from
¹⁴⁶ statistical heuristics: participants probabilistically associate certain surface forms—such as genitive
¹⁴⁷ NPs or overt determiners—with being an agreement controller. For example, Lago et al. (2019)
¹⁴⁸ argue that Turkish speakers retrieve genitive-marked attractors as controllers because genitive
¹⁴⁹ case controls agreement in embedded clauses, even though it cannot in matrix clauses. Thus, a
¹⁵⁰ phonological—not functional—syncretism between the nominal modifier and the embedded subject
¹⁵¹ drives attraction. Similarly, Dillon and colleagues argue for sensitivity to ‘looking like a controller’
¹⁵² in languages like Romanian and Hindi (Bhatia and Dillon, 2022; Bleotu and Dillon, 2024). For
¹⁵³ instance, Bleotu and Dillon (2024) found that Romanian attractors induced errors only when they
¹⁵⁴ surfaced with a determiner (as opposed to bare forms). Since only nouns with determiners can
¹⁵⁵ control agreement in Romanian, they argue that participants associate the presence of a determiner
¹⁵⁶ with controllerhood. Likewise, in English, Schlueter et al. (2018) show that the coordinator ‘and’
¹⁵⁷ causes attraction even without semantic plurality because it is statistically associated with the
¹⁵⁸ plural feature. These explanations suggest that the cue-chunk match is not strictly categorical, but
¹⁵⁹ influenced by surface-level statistical associations (Engelmann et al., 2019).

¹⁶⁰ A similar account extends to Russian. While genitive-marked nouns can serve as subjects in
¹⁶¹ negative inversion constructions, they do not control verbal agreement in these contexts. Cru-
¹⁶² cially, however, they remain active controllers within the noun phrase, triggering number or gender
¹⁶³ marking on modifiers (e.g., surfacing as feminine *ni odnoy* with a feminine head, contrasting with
¹⁶⁴ masculine *ni odnogo* in 3) (Babby, 2001; Partee and Borschev, 2004). In contrast, Czech does not
¹⁶⁵ allow genitive subjects, and thus not license these controller properties in subject positions.

- ¹⁶⁶ (3) ..., tam ne rabotaet ni odnogo inženera.
... there NEG works not one.GEN engineer.GEN
¹⁶⁷ ‘..., there hasn’t been a single engineer working there.’

¹⁶⁸ Motivated by these alternative accounts and conflicting findings (Bock and Eberhard, 1993;
¹⁶⁹ Lacina and Chromy, 2022) along with the theoretical importance of such proposal, we test the
¹⁷⁰ phonological modulation hypothesis in two high-powered experiments: whether a syntactically in-
¹⁷¹ eligible controller, but still a possible subject, can induce attraction solely through morphophono-
¹⁷² logical overlap matching the agreement suffix in form and semantics. To this end we capitalize
¹⁷³ on the shared surface form of verbal and nominal plural marking (*-lAr*) in Turkish to target this
¹⁷⁴ question. We use reduced relative clauses (RRCs) where the plural-marked verb appears as the
¹⁷⁵ attractor (4). Crucially, this *-lAr* syncretism is not feature-ambiguous; it is a form-only overlap

¹⁷⁶ lacking the possibility of being a potential controller. Even when a headless RRC alone surfaces as
¹⁷⁷ a subject, it cannot control agreement (5).

¹⁷⁸ (4) Gör-dük-ler-i çocuk koş-tu-(^{*lar}).
go-NMLZ-PL-POSS kid[NOM] run-PST-(^{*PL})

¹⁷⁹ ‘The kid that (they) saw ran.’

¹⁸⁰ (5) Gör-dük-ler-i koş-tu-(^{*lar}).
go-NMLZ-PL-POSS run-PST-(^{*PL})

¹⁸¹ ‘(The kid) that (they) saw ran.’

¹⁸² In Experiment 1, we tested the form hypothesis by comparing sentences with verbal attractors
¹⁸³ to sentences with canonical nominal attractors in Turkish. Experiment 2 then tested the form
¹⁸⁴ hypothesis more directly by only using verbal attractors. We expected that if surface-overlap
¹⁸⁵ can modulate relevant memory representations for dependency resolutions, we would see similar
¹⁸⁶ attraction results with nominal and verbal attractors. However, if participants are tracking an
¹⁸⁷ higher order cue that is relevant for being a possible controller, then the verbal attractors, due to
¹⁸⁸ their inability to control agreement, would not introduce agreement attraction effects even though
¹⁸⁹ their high morpho-phonological similarity.

¹⁹⁰ Across both experiments, we found no evidence that verbal -lAr induces attraction, even when
¹⁹¹ canonical nominal attractors are present in the same session. This pattern aligns with prior find-
¹⁹² ings in general attraction literature and Turkish agreement attraction, namely surface-form overlap
¹⁹³ alone does not derive agreement illusions. Rather, attraction appears to depend on abstract feature
¹⁹⁴ overlap between potential controllers and agreement probes, and possibly statistical associations
¹⁹⁵ between the strings and their controllers. In this light, findings of Slioussar (2018) are best ana-
¹⁹⁶ lyzed as a possible increased association between genitive marking and possible subjecthood and
¹⁹⁷ being an agreement controller, which is not possible in Czech, and thus no attraction (Lacina and
¹⁹⁸ Chromy, 2022). By doing so, we hope to clarify how cue-mechanisms are employed and the role of
¹⁹⁹ phonological overlap in sentence processing.

²⁰⁰ 2 Experiment 1: Testing Surface-Form Overlap

²⁰¹ 2.1 Participants

²⁰² We recruited 95 undergraduate students from Anonymous University to participate in the experi-
²⁰³ ment in exchange for course credit. All participants were native Turkish speakers, with an average
²⁰⁴ age of 21 (range: 18 – 30).

²⁰⁵ 2.2 Materials

²⁰⁶ We used 40 sets of sentences like Table 1, in which we manipulated (i) the number of the attractor,
²⁰⁷ (ii) the type of the attractor, and (iii) the number agreement on the verb. Both plural markings

²⁰⁸ were marked with the suffix *-lAr*, while the singular number and singular agreement were marked
²⁰⁹ by its absence.

Table 1: Experimental conditions. The Attractor was manipulated for number and type. The Verb was manipulated to match or mismatch the head noun (always singular), creating Grammatical and Ungrammatical conditions.

				Grammaticality (Verb Suffix)	
	Attr. Type	Attr. Num	Attractor	Grammatical	Ungrammatical (*)
Verbal	SG	Tut-tuğ-u	zipla-di	*zipla-di-lar	
		hire-NMLZ-POSS	jump-PST	jump-PST-PL	
	PL	Tut-tuk-lar-i	zipla-di	*zipla-di-lar	
		hire-NMLZ-PL-POSS	jump-PST	jump-PST-PL	
Nominal	SG	Milyoner-in	zipla-di	*zipla-di-lar	
		millionaire-GEN	jump-PST	jump-PST-PL	
	PL	Milyoner-ler-in	zipla-di	*zipla-di-lar	
		millionaire-PL-GEN	jump-PST	jump-PST-PL	

(6) *Verbal Attractor Conditions*

[**Attractor**] aşçı mutfak-ta sürekli [**Verb**]
 hire-NMLZ-(PL)-POSS cook kitchen-LOC non.stop jump-PST-(PL)
 ‘The [*Attr.* **hired_{pl}/hired_{sg}**] cook [*Verb* **jumped_{pl}/jumped_{sg}**] in the kitchen non-stop.’

(7) *Nominal Attractor Conditions*

[**Attractor**] aşçı-sı mutfak-ta sürekli [**Verb**]
 millionaire-(PL)-GEN cook-POSS kitchen-LOC non.stop jump-PST-(PL)
 ‘The [*Attr.* **millionaires’/millionaire’s**] cook [*Verb* **jumped_{pl}/jumped_{sg}**] in the kitchen non-stop.’

²¹⁰ Verbal attractor conditions featured complex subject NPs containing a bare head noun and a
²¹¹ reduced relative clause acting as the attractor (e.g., ‘tuttukları aşçı’, ‘the hired cook’). Because
²¹² nominal plural marking is mandatory and the head noun was always singular, plural verb agreement
²¹³ rendered these sentences ungrammatical. Nominal attractor conditions, featuring nominal attrac-
²¹⁴ tors such as ‘milyonerlerin aşçısı’ (‘the millionaires’ cook’) were taken from Türk and Logačev
²¹⁵ (2024). To prevent participants from associating plural verbs with ungrammaticality, fillers were
²¹⁶ balanced between grammatical sentences with plural verbs and ungrammatical sentences with sin-
²¹⁷ gular verbs.

²¹⁸ 2.3 Procedures

²¹⁹ The experiment was conducted online via Ibex Farm (Drummond, 2013), lasting approximately 25
²²⁰ minutes. After providing informed consent and demographic details, participants read instructions
²²¹ and completed nine practice trials.

²²² Each trial began with a 600 ms blank screen, followed by a centered, word-by-word RSVP
²²³ presentation (30 pt font, 400 ms duration, 100 ms inter-stimulus interval). Upon the prompt,

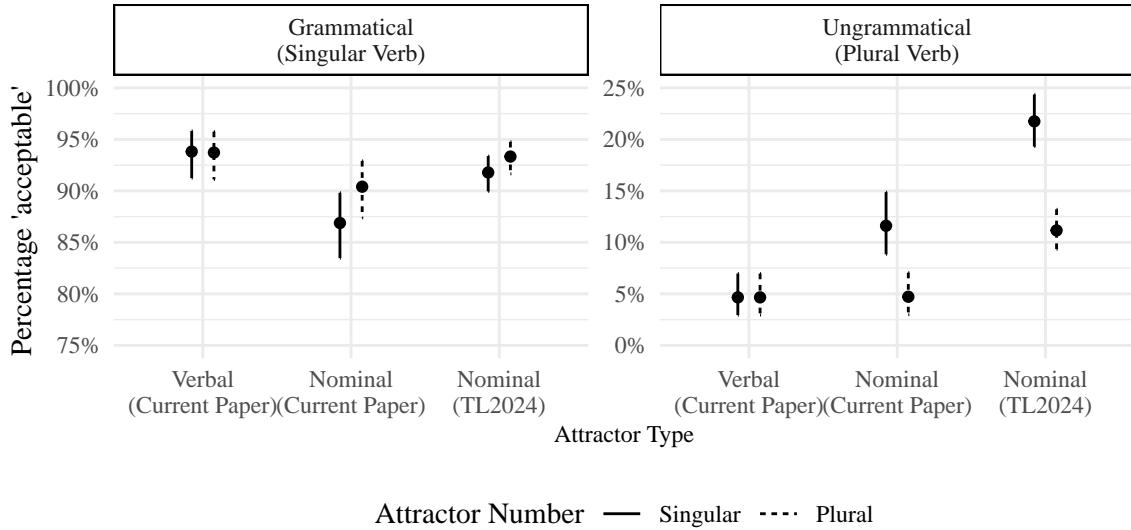

Figure 1: Mean proportion of ‘acceptable’ responses by grammaticality, attractor number and attractor type. Error bars show 95% Clopper–Pearson confidence intervals.

224 participants judged sentence acceptability as quickly as possible by pressing ‘P’ (acceptable) or
 225 ‘Q’ (unacceptable). A red warning message appeared during practice trials—but not experimental
 226 trials—if responses exceeded 5,000 ms. Participants pressed the space bar to advance to the next
 227 item.

228 The study included 40 experimental and 40 filler sentences. Experimental items were distributed
 229 across four lists using a Latin-square design, ensuring each participant viewed only one list con-
 230 taining one version of each item.

231 2.4 Analysis and Results

232 Participants showed high accuracy in both grammatical ($M = 0.95$, $CI = [0.94, 0.96]$) and ungram-
 233 matical filler sentences ($M = 0.06$, $CI = [0.05, 0.07]$), indicating that they understood the task and
 234 performed it reliably.

235 Figure 1 presents the overall means and credible intervals for ‘yes’ responses across experimental
 236 conditions, as well as the previous data from Türk and Logačev (2024), which is quite similar
 237 to the magnitude of Lago et al. (2019). As shown, in our study, participant gave more ‘yes’
 238 responses to ungrammatical sentences with plural genitive-marked nominal attractors ($M = 0.12$,
 239 $CI = [0.09, 0.15]$) compared to their singular counterparts ($M = 0.05$, $CI = [0.03, 0.07]$).

240 However, similar increase in acceptability was not found with verbal attractors ($M = 0.05$ and
 241 0.05 , $CI = [0.03, 0.07]$ and $[0.03, 0.07]$ for singular and plural attractors, respectively). Participants
 242 rated grammatical sentences similarly independent of the attractor number or attractor type.

243 Our maximal Bayesian models also showed similar results, assuming a Bernoulli logit link. Our
 244 main research question was whether verbal attractors induced attraction effects. We also wanted to

245 verify the canonical attraction effects in Turkish with nominal attractors. To that end, we included
246 genitive marked nominals from data from our experiment and Türk and Logačev (2024). The
247 model was fitted to the binary *yes/no* responses and assumed uninformative priors. Grammaticality
248 and Attractor Number was sum coded (grammatical = 0.5, ungrammatical = -0.5; plural = 0.5,
249 singular = -0.5). Attractor Type (Nominal-Current, Nominal-TL24, Verbal) was represented by
250 two orthogonal Helmert contrasts: an initial contrast comparing verbal attractors to the average of
251 the two nominal conditions (Nominal-Current = -1/6, Nominal-TL24 = -1/6, Verbal = 1/3) and
252 another contrast comparing the two nominal conditions (Nominal-Current = 1/3, Nominal-TL24
253 = -1/3, Verbal = 0). All fixed effects and their interaction were included, along with random
254 intercepts and slopes for both subjects and items.

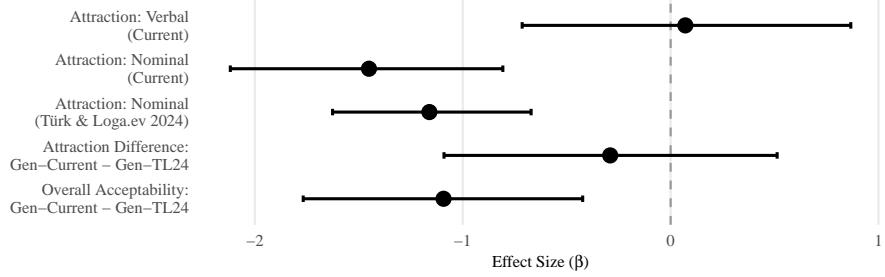

255 We present posterior summaries of estimated regression effects from our model in Figure 2a along
256 with a nested model coefficients in Figure 2b for verification. Our model showed a robust attraction
257 in both nominal attractor cases, with strongly negative effects for our nominal items ($M = -1.45$,
258 $CI = [-2.12, -0.81]$, $P(<0) = >0.99$) and items from Türk and Logačev (2024) ($M = -1.16$, $CI =$
259 $[-1.63, -0.67]$, $P(<0) = >0.99$). More importantly, our model found no evidence for an attraction in
260 verbal attractor conditions ($M = 0.07$, $CI = [-0.71, 0.87]$, $P(<0) = 0.44$), verifying our observations
261 in the descriptive statistics. We did not find an evidence for a difference in magnitude of attraction
262 between the two nominal-type attractors ($M = -0.29$, $CI = [-1.09, 0.51]$, $P(<0) = 0.72$), suggesting
263 the presence of an additional conditions did not affect attraction magnitudes. Finally, we found
264 strong evidence for a decreased overall acceptability for nominal items in our experiment ($M =$
265 -1.09 , $CI = [-1.77, -0.42]$, $P(<0) = >0.99$), suggesting the within-experimental distribution did
266 affect overall acceptability, but not attraction.

267 2.5 Discussion

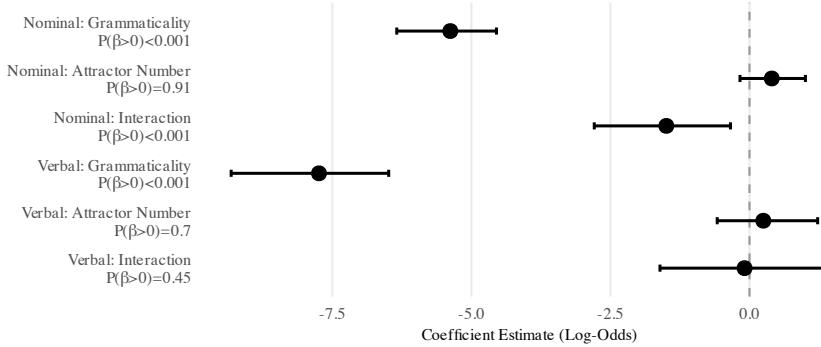

268 Experiment 1 found no evidence that phonological overlap between nominal and verbal plural
269 morphemes in Turkish induces attraction. Participants reliably rejected ungrammatical sentences
270 with plural-marked verbal attractors, contrasting with the canonical attraction effects observed for
271 nominal attractors. This indicates that the verbal plural marker *-lAr* does not generate interference
272 comparable to nominal plurals.

273 Our results and between-experiment comparisons indicate that within-experiment statistics—
274 specifically, exposure to verbal attraction items—did not substantially reduce attraction magnitude.
275 However, overall acceptability for nominal attractor sentences was lower than in Türk and Logačev
276 (2024). This aligns with prior work showing that trial distributions modulate judgments. While
277 previous studies drove this effect via instructions or fillers (Hammerly et al., 2019; Arehalli and
278 Wittenberg, 2021), we demonstrate that experimental conditions and the presence of an effect in a
279 condition subset also modulate overall acceptability, but surprisingly not the attraction.

280 A potential concern is that our mixed design—combining canonical nominal attractors with
281 verbal ones—influenced response patterns. The presence of robust nominal attraction may have
282 altered participant strategies, potentially masking weaker verbal effects (Hammerly et al., 2019;

(a) Posterior estimates of attraction magnitudes and dataset contrasts. The top three rows display the attraction effect size (grammaticality \times attractor number interaction) for each condition. The bottom two rows explicitly plot the difference between our Experiment 1 and Türk and Logačev (2024) nominal conditions in terms of attraction strength and overall acceptability (baseline rating).

(b) Posterior coefficient estimates (log-odds) from two separate Bayesian mixed-effects logistic regression models fitted to Nominal and Verbal conditions. The models predict 'Yes' responses based on Grammaticality, Attractor Number, and their Interaction. Points indicate posterior means, error bars show 95% credible intervals, and labels display the posterior probability that the coefficient is positive ($P(\beta > 0)$).

Figure 2: Bayesian analysis of Experiment 1 results. Panel (a) presents derived effect sizes along with contrasts between the current and Türk and Logačev (2024) nominal conditions. Panel (b) details the specific model coefficients for the Nominal and Verbal subsets.

²⁸³ Türk, 2022). To determine if the absence of verbal attraction in Experiment 1 was genuine rather
²⁸⁴ than a distributional artifact, Experiment 2 removed all nominal attractors. This design tests
²⁸⁵ whether the null effect persists when verbal morphology is the sole potential source of interference.

²⁸⁶ 3 Experiment 2: Isolating Verbal Attractors

²⁸⁷ 3.1 Participants, Materials, and Procedure

²⁸⁸ Eighty native Turkish speakers (mean age = 21, range: 18–31) were recruited. We utilized the
²⁸⁹ same verbal attractor items and fillers from Experiment 1, removing all nominal attractor trials.
²⁹⁰ The experimental procedure was identical to Experiment 1.

²⁹¹ 3.2 Analysis and Results

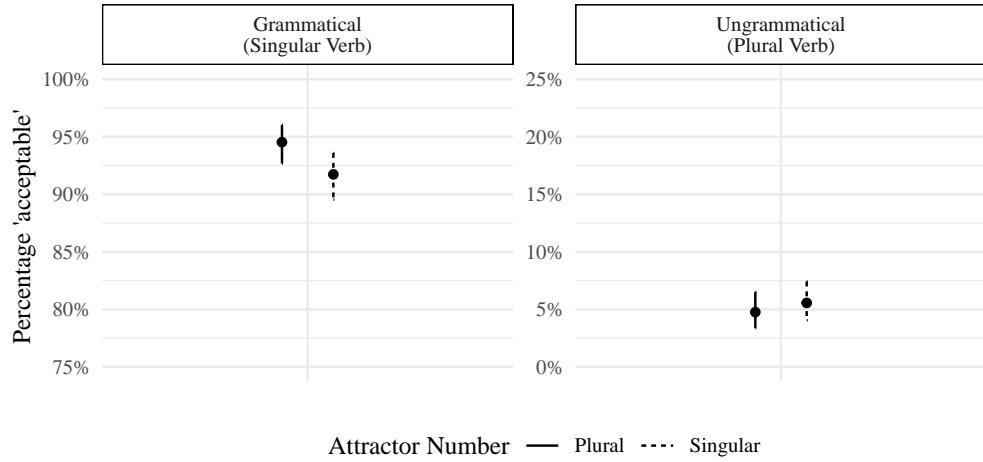

²⁹² Participants showed high accuracy in both grammatical ($M = 0.94$, $CI = [0.92, 0.95]$) and ungrammatical filler sentences ($M = 0.08$, $CI = [0.07, 0.1]$), indicating that they understood the task and
²⁹³ performed it reliably.

²⁹⁵ Figure 3a presents the overall means and credible intervals for ‘yes’ responses across experimental
²⁹⁶ conditions. As shown, ungrammatical sentences with plural attractors were rated as acceptable as
²⁹⁷ their counterparts with singular attractors ($M = 0.06$ and 0.05 , $CI = [0.04, 0.07]$ and $[0.03, 0.07]$
²⁹⁸ for singular and plural attractors, respectively).

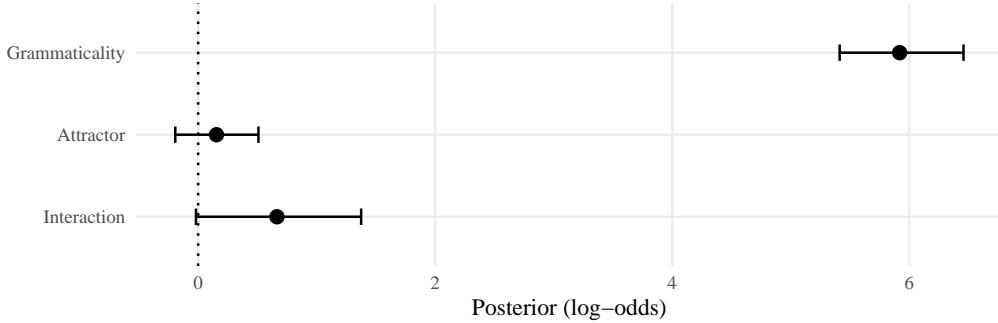

²⁹⁹ On the other hand, accuracy in grammatical conditions was modulated by the number of the
³⁰⁰ attractor in an unexpected way. Participants rated grammatical sentences with singular attractors
³⁰¹ as grammatical less often ($M = 0.92$, $CI = [0.90, 0.94]$) compared to their counterparts with plural
³⁰² attractors ($M = 0.95$, $CI = [0.93, 0.96]$).

³⁰³ These descriptive trends were confirmed by our Bayesian mixed-effects models implemented in
³⁰⁴ brms, assuming a Bernoulli logit link. The model was fitted to the binary *yes/no* responses and
³⁰⁵ included fixed effects for Grammaticality and Attractor Number and their interaction, and random
³⁰⁶ intercepts and slopes for both subjects and items.

³⁰⁷ Posterior estimates are summarized in Figure 3b. The model revealed a positive effect of grammaticality ($\beta = 5.92$ [$5.41, 6.46$], $P(\beta > 1.00)$), but no reliable main effect of attractor number ($\beta =$
³⁰⁸ 0.15 [$-0.19, 0.51$], $P(\beta > 0.81)$). On the other hand, there was a small but positive interaction ($\beta =$
³⁰⁹ 0.66 [$-0.02, 1.38$], $P(\beta > 0.97)$). To clarify the effects’ presence in grammatical only, we fitted two
³¹⁰ more models that is fitted to the subset of the data. While the model fitted to grammatical condi-
³¹¹ tions only showed an effect of attractor number $+(\beta = 0.51$ [$0.06, 1.00$], $P(\beta > 0.99)$), the model
³¹² fitted to ungrammatical conditions, attraction relevant conditions, did not provide evidence for the
³¹³ effect of number manipulation ($\beta = -0.05$ [$-0.45, 0.37$], $P(\beta > 0.99)$). These results suggest that
³¹⁴ the presence of a plural attractor did not increase the acceptability of ungrammatical sentences,
³¹⁵ nor was this relationship modulated by grammaticality.

(a) Mean proportion of ‘acceptable’ responses. The facet columns distinguish between Grammatical and Ungrammatical conditions, while line types indicate Attractor Number. Error bars represent 95% Clopper–Pearson confidence intervals.

(b) Posterior coefficient estimates from the Bayesian mixed-effects logistic regression model. The plot displays the posterior means (points) and 95% credible intervals (horizontal bars) for the fixed effects of Grammaticality, Attractor Number, and their Interaction. The estimates are on the log-odds scale.

Figure 3: Overview of results for Experiment 2. Panel (a) presents the descriptive statistics for acceptability judgments, while Panel (b) details the inferential statistics from the fitted model.

³¹⁷ **3.3 Discussion**

³¹⁸ Experiment 2 replicated the verbal attractor conditions from Experiment 1 in isolation and again
³¹⁹ revealed no evidence for agreement attraction driven by verbal plural markers. Ungrammatical
³²⁰ sentences with plural marked main verbs were rejected at similar rates regardless of whether the
³²¹ reduced clause verb bore plural *-lAr* or not, and there were no reliable effects of attractor number or
³²² interactions involving attractor number. This confirms that the absence of a verbal attraction effect
³²³ in Experiment 1 was not due to the presence of nominal attractor items or to within experiment
³²⁴ item statistics.

³²⁵ Unexpectedly, grammatical sentences with singular attractors were judged less acceptable than
³²⁶ those with plural attractors. This effect is unlikely to reflect agreement attraction, since it arises in
³²⁷ the opposite direction. One possibility is that it results from an interaction between plausibility and
³²⁸ referential availability. The plural morpheme can license a more general interpretation by allowing
³²⁹ an unspecific reference, whereas the singular reduced relative clause more strongly invites a specific
³³⁰ referent, which may be less accessible in the context of the task. We do not pursue this explanation
³³¹ further, as it falls outside the scope of the present paper.

³³² **4 General Discussion**

³³³ We investigated whether surface-overlap advantage seen in reading times and comprehension ques-
³³⁴ tions can bleed into dependency resolution. Recent work by Slioussar (2018) argued that an acci-
³³⁵ dental surface-overlap with a nominative plural form may result in activation of relevant cues even
³³⁶ though the syntactic analysis of such a noun is clearly genitive singular. However, modulation of
³³⁷ agreeement-relevant cues seems to be gated by being a possible controller in other relevant work
³³⁸ in syncretism, and similar manipulations in English and Czech were unable to find a phonological
³³⁹ modulation.

³⁴⁰ Using two speeded acceptability judgment experiments, we disentangled the statistical property of
³⁴¹ being a controller from a surface overlap. Turkish provides a useful test case because the plural *-lAr*
³⁴² appears both on verbs and on nouns, but only noun phrases can control agreement. If phonological
³⁴³ overlap alone can activate controller-relevant cues, then plural-marked verbs in reduced relative
³⁴⁴ clauses should induce attraction effects even though they never control agreement.

³⁴⁵ Across both experiments, we found that Turkish attraction is determined by being a potential
³⁴⁶ controller rather than merely resembling one. Participants did not accepted ungrammatical sen-
³⁴⁷ tences with containing plural verbal attractors more often than their singular counterparts. This
³⁴⁸ absence of attraction persisted with or without a robust attraction with nominal attractors in the
³⁴⁹ same session.

³⁵⁰ These results indicate that attraction depends on abstract feature overlap with potential con-
³⁵¹ trollers, not on surface-form similarity. This pattern converges with prior results in English and
³⁵² Turkish that failed to find attraction for pseudoplural or phonologically plural forms (Bock and
³⁵³ Eberhard, 1993; Haskell and MacDonald, 2003; Nicol et al., 2016), but appears to stand in contrast

³⁵⁴ to findings from Russian (Slioussar, 2018).

³⁵⁵ While the most obvious difference is syntactic—our non-attracting elements were verbs, whereas
³⁵⁶ the attracting elements in Russian were nouns (Slioussar, 2018)—this distinction alone is insuffi-
³⁵⁷ cient, as prior work shows that even pseudoplural nouns in English and the same surface-overlap
³⁵⁸ in Czech fail to attract (Bock and Eberhard, 1993; Lacina and Chromý, 2022). We propose in-
³⁵⁹ stead that the parser ‘gates’ its search based on an element’s abstract potential to be a controller.
³⁶⁰ The Russian genitive noun, despite its surface form, is recognized as an element that can control
³⁶¹ agreement in other constructions, thus passing this abstract gate. Our Turkish verbal attractors or
³⁶² Czech genitive nouns, by contrast, lack this potential entirely; they can never be controllers. They
³⁶³ therefore fail this gating, and no attraction is observed, despite the perfect phonological overlap.

³⁶⁴ This interpretation aligns with cross-linguistic findings showing that attraction is strongest when
³⁶⁵ the attractor bears case or number morphology that can be associated with subjects or agreement
³⁶⁶ controllers (Lago et al., 2019; Bhatia and Dillon, 2022; Bleotu and Dillon, 2024). In other words,
³⁶⁷ it is not form overlap per se, but feature ambiguity or a statistical association with controllerhood
³⁶⁸ that matters. Earlier formulations of these models left open whether ‘looking like’ a controller or
³⁶⁹ ‘being able to be’ a controller was critical. The present high-powered results from Turkish favor
³⁷⁰ the latter: only morphologically licensed controllers, or those with a genuine abstract potential to
³⁷¹ be one, engage in attraction.
